Initial changes during vision therapy

We did an intensive training across the time of a week with Atlas and we started noticing some pretty distinct changes within just a few days of vision therapy.

And those were a significant decrease in the length of time or even the frequency of meltdowns. We saw immediately more attention So we could, prior to this, we would say Atlas's name four or five times with no recognition and no interaction.

Improved attention and patience

And, you know, even while we were during training, I would his name once and he would just perk up and look up. His patience has changed dramatically.

Then we saw an ongoing series of changes with him. that are around his overall behavior, his temperament, and then also his, you know, scholastic, mathematic abilities actually at school.

So interestingly enough, we have some test results from before and after doing vision therapy where he was at or below the benchmark for his age group.

Academic gains after therapy

And then within months of doing vision therapy, far exceeded test results of his other peers. In fact, he's now in the 99th percentile for mathematics for his age group and the 90th, percentiles for reading for this age, which he was in, the 40th per centile or below.

in both those categories prior to vision therapy. And we've lived in the same house, we eat the the food, have the friend groups. There's really no other possible dynamics that could have changed this except for the intensive training that we did with Dr.
